

ABSTRACT OF THE DISCLOSURE

When log data is stored in a shared area of RAM provided in a multifunction device, a personal computer generates and transmits a log page having links to image  
5 data. These links are links to files (image data) registered in a log table. The log table includes a list of content identified by the log data stored in the RAM of the multifunction device. This log data can identify a file only when the multifunction device determines that the image  
10 data may be recorded. Accordingly, the personal computer can generate log pages having links to files for which image data can be recorded, that is, files that can be made public via a communication network.
